Machine Markets: Current Numerical Evidence Supplement

Pratik Niroula and Prashant Niroula

October 8, 2026

This supplement documents the current reconstructed questions and numerical references. Its intervals are exploratory references under the stated assumptions, not certificates of serial confidence coverage, causal learning attribution, source rights for every transformation, market calibration or independent specialist review. Historical literals are preserved in earlier artifacts and superseded by the named reconstructions.

1 Sources, Representation and Protocols

The original 768 Binance study units are reproduced from current official archives with official SHA256 and ZIP CRC checks. Historical download-time hashes were not preserved. All three recorded one-second files match version 1 of Nielsen's primary release byte for byte (uploader-declared CC0). The January CSV exactly reproduces from version 1 of the primary Parquet distribution (uploader-declared Apache 2.0); exchange/contract metadata are absent. The FI-2010 primary record declares CC BY 4.0, while original archive acquisition and local stock/day transformation authentication remain open. Current Binance Vision terms specify CC BY-NC-SA 4.0; final derivative publication must reflect the provider terms.

The recorder baseline admits occupied ten-second bins, including partial bins. Its EMA resets at missing whole bins and continues across contiguous dates; regressions split dates and bin gaps. The strict sensitivity requires ten observed seconds per bin and resets across the resulting gaps. Recorded flow is a constructed feature; source-byte authentication does not authenticate an executed-volume accumulation window. The original Binance reconstruction separately requires complete bins and resets by date/gap. Equity uses event-indexed supplied labels, not authenticated company identities. January uses top-quote OFI, not executed trades.

2 Strict Recorder Completeness Sensitivity

Strict constructions use EMA 300, burn 150 ten-second states and sufficiently long date/gap segments. Counts and date-Student references are calculated from separately saved segment estimates. Baseline partial-bin counts are 75(BTC), 72(ETH), 69(ADA); removing those bins also changes subsequent EMA burn and segment eligibility.

Table 1: Every strict recorder construction; all questions retained.

Asset	Construction	Dates	Segments	Transitions	Q	Date reference
BTC	x_observed	13	70	92591	0.0010800	[0.0004854, 0.0016746]
BTC	x_forward	13	70	92521	0.0091772	[0.0060301, 0.0123244]
BTC	return_observed	13	70	92591	0.0005381	[-0.0007296, 0.0018059]
ETH	x_observed	13	72	92141	0.0007072	[0.0002962, 0.0011181]

ETH	return_observed	13	72	92141	0.0003063	[-0.0004946, 0.0011071]
ADA	x_observed	13	68	92874	0.0004148	[-0.0000503, 0.0008798]
ADA	x_forward	13	68	92806	0.0061002	[0.0046502, 0.0075502]
ADA	return_observed	13	68	92874	-0.0001126	[-0.0009599, 0.0007347]

3 Original-Panel Lag Controls and Date References

All 768 study units are reconstructed without filling. L counts ten-second bars, so $L = 90$ is 900 seconds. Segment estimates combine within each date using transition weights. The following intervals use equal-weight sampled dates, with serial-dependence and selection limitations.

Table 2: Full six-horizon original-panel lag ledger.

Pair	L	Seconds	Dates	Mean Q_L	Date reference
BTC	1	10	96	0.0006350	[0.0002804, 0.0009896]

4 Calendar Dependence Sensitivity

Calendar Bartlett weights depend on actual elapsed days, rather than treating irregular sampled dates as equally spaced. The Gaussian references require additional mixing/stationarity conditions. The 32-reference grid is retrospective and does not establish finite-sample or causal confidence coverage.

Table 3: All calendar covariance references.

Construction	Index	Days	Dates	Mean	Gaussian reference
legacy	Q	30	96	0.0081536	[0.0072655, 0.0090417]

5 Fee Comparison: Reference Sensitivity

The four-regressor BTC-by-post specification has 192 rows, one treated asset, eight asset groups and 24 date groups. Non-rejection does not establish causal invariance. The legacy placebo rank is not a randomized-treatment probability. The old 0.007 equivalence margin is inappropriate relative to the corrected baseline magnitude.

Table 4: Corrected observed-flow coefficient under all declared references.

Index	Reference	df	Effect	SE	p	Reference interval
Q	classical	188	-0.0001057	0.0004038	0.793794	[-0.0009023, 0.0006909]

6 Covariance Model Restrictions

All fixed centering/bandwidth cases are retained, with six starts each. The model uses unrestricted stable transition and positive-definite innovation parameterization. The 11 moments and seven parameters give a four-degree

asymptotic reference. Rejection is evidence against maintained restrictions for that construction, not validation of latent learning or a causal model.

Table 5: Complete maintained-model diagnostic grid.

Asset	Case	Rows	df	J	p	Q

7 Joint Cross-Venue Association

The joint four-variable VAR uses 11 matched April 2021 dates, complete ten-second bins, segment effects and actual timestamps. Generalized shares are normalized by row. All 24 orthogonal orderings are retained. Quote-currency and timing differences and missing structural shock identification prevent a causal transmission claim.

Table 6: All six horizons for both predictive directions.

Asset	Seconds	ρ	BN-to-recorder	Ordering range	Recorder-to-BN

8 Switching Models and Forecast Boundaries

The scalar switching regression uses exact joint transition posteriors, four starts, two variance floors, two specifications and six datasets. Forecasts use seven chronological expanding test dates, April 13–19, 2021. All MSE references span zero; every full-coefficient versus variance-only reference also spans zero. Selected iteration-limit fits and variance-floor sensitivity remain part of the result.

Table 7: Every reported switching forecast comparison.

Dataset	Comparison	MSE change	Date reference	Density change	Date reference
BTC_x	Var–OLS	-0.10456	[-0.31673, 0.10760]	0.69176	[0.57185, 0.81167]

9 Replayed Financial Scenarios

The 22,000 existing funded paths are rerun with their saved seed and independently reconstructed cash/mark identity. Capacity scales the 25-share inventory limit at fixed initial equity 10,000. Effective anchor is 0.80 rather than nominal 0.40. All effective systems in that grid are supercritical; inventory-limit hits are sticky occurrences, not a permanent ban or default. Independent inventory projection sensitivity leaves the reported hit counts unchanged.

Table 8: All 22 funded cells, 1,000 paths each.

Nominal S	Effective S	Capacity	Shock	Hits	Defaults	Mean minimum equity
0.70	1.10	0.5	-0.2	691	0	9998.9458
0.70	1.10	0.5	-0.6	1000	0	9999.9521
0.70	1.10	1.0	-0.2	0	0	9999.1197
0.70	1.10	1.0	-0.6	0	0	9998.6558
0.70	1.10	2.0	-0.6	0	0	9997.4167
0.70	1.10	2.0	-2.0	0	0	9983.7661

1.18	1.58	1.0	-0.6	1000	0	9994.9768

Nominal S	Effective S	Capacity	Shock	Hits	Defaults	Mean minimum equity
1.18	1.58	1.0	-0.8	1000	0	9994.9768
1.18	1.58	2.0	-1.0	1000	0	9979.7590
1.18	1.58	2.0	-2.0	1000	0	9979.7559

The separate lagged-memory dealer experiment uses 400 paths per cell. Its archived halt flag combines nonpositive equity and a position-limit event. These causes are not separated in the saved count, and its flow calibration remains model moments rather than real queue fills. All 48 cells and exact binomial references are retained below.

Table 9: Complete conditional dealer replay; a limit event is not an observed market default.

S	Leverage	Mode	Halts	Paths	Rate	Exact binomial reference
0.50	10	feedback	44	400	0.1100	[0.08107, 0.14485]

10 January Retrospective Forecast Reconstruction

The existing authenticated January sample now has its own forecast computation. Quote OFI and the gap-reset EMA 120 retain the same 152 eligible date/gap segments and 844,621 baseline transitions. Regression lags split dates/gaps. Six initial training dates precede each of six expanding evaluation dates, January 15–20, 2023. All four lag horizons are retained; normalization and coefficients use training observations only. The one-second lag grid and protocol are retrospective, rather than an untouched holdout or preregistered selection. Positive mean reductions are predictive associations, with six serial dates and no multiple-comparison or causal guarantee.

Table 10: All existing-sample January AR-minus-VAR losses; scale is training SD.

Lag sec	Target	Dates	AR MSE	Mean reduction	Date reference	Reduction percent
1	price	6	0.0203504	0.0003750	[0.0003470, 0.0004030]	1.84275
1	flow	6	0.7218236	0.0001187	[-0.0000583, 0.0002958]	0.01645
2	price	6	0.0203144	0.0003624	[0.0002907, 0.0004341]	1.78394
2	flow	6	0.7195081	0.0008158	[0.0005398, 0.0010918]	0.11339

11 Financial Information and Publication Boundaries

The main manuscript and central-result review packet now specify the physical input, positive price-response geometry, refreshed average-book execution, actual cash/inventory and distinct counterparty/probe-trader funding. A restricted noisy-price observer faces the stated resource orders. Exact marked equity and naturally excited price blocks change that experiment. These constructed financial models do not authenticate actual impact, queue fills, funding, collateral, positions or a financial data-noise contract for the recorded samples.

Existing learned-policy aggregate outputs are audited without new training: their asserted high R-squared conclusion is contradicted by the saved values and constant-action substitution, and the source lacks a sufficient checkpoint chain and genuine queue-fill calibration. The current manuscript uses none of those outputs as an operational safety certificate.

The historical flash-crash script assigns or simulates its coefficients, contains no historical TAQ/account ingest and changes several counterfactual inputs at once. Its underlying research question remains open, and its original outputs are retained as illustrations. Original equity archive acquisition, representation/stock mapping, real financial calibration, defensible causal inference where needed and independent specialist assessment remain publication gates.

Named source/evidence receipts accompany this supplement; a computation, source hash or clean PDF is not scientific or publication closure.
